Because we don't
want that
anymore

A word on system versioning:

Solo versioning

When you are working on a file, alone,
you will usually use this kind of system
versioning

But what happens when you are not
alone anymore ?

Centralized Version control system

A common and easy way to do this is to have a share database and each change from someone will be a new version

Distributed version control

But to have a lower risk to lose your data and be able to work even you don't have access to the server we can have all a copy of the version database.

Branching, or when version1.bis begin

Sometimes we want to change something, but first when we are working on it, this new version will maybe not work anymore and secondly maybe you are not sure that you will keep this feature

So, the natural way is to make a copy of the last version, call it differently and work on this new file.

This is called branching

Particularly useful when you want to work at the same time with two different features, or two different people.

And maybe go crazy ?

In 2005 the Linux development community (and in particular Linus Torvalds, the creator of Linux) developed their own open source tool: Git.

Some of the goals of the new system were as follows:

- Speed
- Simple design
- Strong support for non-linear development (branches)
- Fully distributed
- Able to handle large projects

Some useful terminal commands

Git can be used entirely or partially through a text editor such as VSCode, RStudio, or Vim, but this can be limiting. Learning the CLI (command line interface) helps you truly understand what you're doing, and that understanding carries over to any text editor you use.

For that we will need 3 basics commands in your terminal.

When you open your terminal, you arrive at your root directory, to move inside you will need to:

- see where you are: **pwd** for print working directory
- see where you can go: **ls** for list
- Move: **cd [directory]** for change directory

ls -force for windows or ls -la for linux/mac to see hidden files

cd .. to go back
cd ~ to go back to your root directory

Questions and next part
